Title: Evaluating Marketplace Interface Design for Suspicious Seller Detection

Idea: Online marketplaces have become a common place for buying and selling products, but users may encounter fraudulent sellers who use fake reviews, misleading product descriptions, or limited account histories to appear trustworthy. While users often rely on seller ratings and reviews to make purchasing decisions, the way this information is presented may affect how quickly and accurately they can identify suspicious sellers. This project will investigate whether the design and organization of marketplace interfaces influence users' ability to recognize potentially fraudulent sellers. Two interface designs will be developed for comparison. The first will represent a conventional marketplace, where seller ratings, reviews, account details, and other relevant information are accessed from separate sections or pages. The second will present the same information in a consolidated interface, allowing users to examine seller details in one place. Participants will complete a set of tasks involving both suspicious and legitimate sellers, and their performance will be evaluated using task completion time, navigation steps, decision accuracy, and usability feedback. The study will also examine whether presenting risk-related information more clearly helps users identify suspicious sellers or instead makes them more likely to distrust legitimate ones.
