```
jshow@Jrod:~/release$ mpirun -np 2 ./hello_mpi pingpong
 Message Size (bytes) | Iterations | Avg RTT (us) | Est. One-way (us)
                    1 |      10000 |        0.439 |             0.220
                    8 |      10000 |        0.904 |             0.452
                   64 |      10000 |        0.364 |             0.182
                  512 |      10000 |        1.255 |             0.628
                 4096 |      10000 |        6.111 |             3.055
jshow@Jrod:~/release$
```

How message size is controlled

- We control the message size by allocating using malloc(message size) and sending that.

How correctness is verified

- We measure the correctness by using the tags not the actual message. We get the tag by doing the iteration with the range and the rank checks the tag it gets and does the reply with the same tag

How pingpong avoids deadlock

- We do a fixed order for the ranks meaning each rank does the send revice. The send receive work together to prevent deadlock

Why we perform timing on rank 0

- Rank 0 completes the rounf trip for each iteration, the lab says we need to do it on zero, it is the one that sees the complete RTT.
